Sample stability
Sample stability is an important issue for DEQAS as samples are sent worldwide at ambient temperature. Solutions of vitamin D and its metabolites are known to be light sensitive and relatively unstable. However, in experiments conducted before the regular dispatch of samples (Fig.1), 25-OHD was shown to be very stable in serum, probably as a result of the tight binding to vitamin D binding protein and the relative opacity of aqueous solutions to UV radiation (ref.2). However the stability studies were performed using a chromatographic method and we cannot guarantee that matrix changes (e.g. a rise in serum pH) that inevitably occur at ambient temperature might not affect the performance of less rigorous methods.

A more recent experiment was conducted using an in-house LC-MS/MS method.

Stability of 25-OHD at 30 degrees C
